

Rung 0: frontier reconstruction

Rebuild local parent, extension, and failure-witness corpus from the Exoo / Ge / Lehavi line.
`frontier_parents.jsonl`,
`extension_cases.jsonl`,
`failure_witnesses.jsonl`

Fast invalidator

`rare_core_tail`: if the first atlas leaves a long uncovered tail, stop scaling.

Rung 1: atlas pass

Canonicalize failure witnesses into a first obstruction dictionary and summarize coverage.
`obstruction_cores.jsonl`,
`atlas_summary.md`

Rung 2: held-out transfer

Freeze family labels, hold out the most non-Exoo-like family, and measure retention.
`transfer_records.jsonl`

Fast invalidator

`anti_exoo_holdout`: if held-out retention collapses, demote or kill H1.

Rung 3: witness safety

Build the witness-survival matrix and run per-filter on/off ablations before any scale-up.
`witness_safety_audit.md`

Fast invalidator

`witness_pressure`: one known witness deletion invalidates the filter bank.

Expansion gate

No broader compute, no H2 opening, and no structural claim beyond route-target status is permitted until all four rungs exist and pass in order.
